### **ATOM INTRODUCTION**

- **<u>ATOM</u>:** Accelerating Therapeutics for Opportunities in Medic
- Open public-private partnership for accelerating drug design using computation-driven drug design
- Use of computational modeling to speed up long drug disco process
- Create machine learning models using AMPL software and tutorials that can learn from how different compounds inter with targets (opioid receptors, hERG, and histamine receptor
- <u>Goals</u>:
- Accelerate drug discovery process
- Improve success rate in translation to patients
- Transforming drug discovery from slow, high-failure proces into rapid, patient-centric model

### **ANALYSIS AND RESULTS**

- Split into 3 teams:
- Team 1: Opioid Receptors

<u>GCNN multi-task vs GCNN single-task:</u>

Multi-task model has slightly higher testing (R<sup>2</sup> score) than the single task model **<u>GCNN multi-task vs Random Forest single task:</u>** 

Multi-task model still has slightly lower testing R<sup>2</sup> than the single task model • Team 2: hERG

<u>GCNN multi-task vs GCNN and Random Forest single-task:</u> Multi-task model has better testing R<sup>2</sup> scores for certain assays compared to the single-task model \*However, it has lower scores in other assays.

• **Team 3**: Histamine Inhibitors

<u>GCNN multi-task vs GCNN and Random Forest single-task:</u>

**Trained on the highly correlated CHRM targets:** Multi-task model has better testing R<sup>2</sup> scores than our single task models for all five targets. Trained on the HRH1, HTR2A, and DRD2 targets:

Multi-task GCNN model only performed better for HRH1.
